**Abstract.** Recycling is one of the better-known strategies for sustainable manufacturing. The aim of the strategy is to focus manufacturers' attention to the finite resources available to mankind. Furniture industry is one of the industries that are currently facing a problem of resource limitation, in particular in the need of wood as raw material. This paper deals with the case of recycling strategy in a lighting manufacturing industry in Indonesia. The manufacturer uses railway track bearing waste as raw material to produce decorated lamps. The problem is to determine which products to be produced subject to the demand of the products and resource constraints. A linear programming was used as an approach to the problem. The result shows that optimal production could be determined by simulating production alternatives of a railway track bearing waste. The optimal production alternative was then decided using a linear programming.

**Keywords:** recycle, railway track bearing, lighting production, linear programming

## 1. INTRODUCTION

A well known definition of sustainable development is given in the 'Brundtland Report' of the World Commission on Environment and Development. In this report the Brundtland Commission defined sustainable development as: "sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 2002).

One of the strategies to implement the concept of sustainable development is sustainable manufacturing. It is a strategy to protect the environment from environmental pollution and degradation by conserving the earth's limited resources and effectively planning for the optimal use of resources and safe disposal waste (Allwood, 2005). The strategies for sustainable manufacturing include inverse manufacturing, recycling, re-manufacturing, reverse logistic, eco-labelling, life cycle assessment, and design for environment (Madu, 2000).

Recycling, re-manufacturing, and re-use have been much interesting as natural resources is going to be depleted. This also happens in wood furniture industry. The industry utilizes virgin wood, which is currently going

to be scarce, as primary raw material. Recognizing the need for wood as primary material, furniture industry has become increasingly attractive through substitution initiatives such as using wood waste as a substitute for virgin wood.

PT Lunar Mulia Kreasi is a company located in Sleman, Yogyakarta, Indonesia that produces furniture, lighting, and bags for domestic and overseas markets. Some of the lighting products are made of railway track bearing waste as the primary material. The products include Bima Lamp (BL), Oval Branch Lamp (OL), Neo Pedati Lamp (PL), Megan Lamp (ML), and Natural Erosi Lamp (NL). Considering the demand for the products and resource availability, the problem is which product(s) and how much to be produced in order to get the highest possibly profit. With regard to that problem, the objective of this study is to determine the optimal production of lighting product at PT. Lunar Mulia Kreasi.

## 2. LIGHTING PRODUCTION

Figure 1 shows the lighting products produced by PT Lunar Mulia Kreasi. Besides railway track bearing waste

(RTB), PT. Lunar Mulia uses other materials and components such as wood and small branch of hardwood trees, accessories lamps, and electrical components to produce the products. Figure 2 shows the RTB used for producing lighting products at PT Lunar Mulia Kreasi. The size and unit price of RTB waste is  $2\text{m} \times 0.22\text{m} \times 0.15\text{m}$  ( $0.066 \text{ m}^3$ ) and Rp 125.000,-. The requirement of RTB for producing each product is shown in Table 1.

\*energy price: Rp 560,-/kW

## 2. MODEL DEVELOPMENT

### 2.1 Notation

In formulating the problem, we use the following notations:

- $C_i$  : total production cost of production alternative  $i$
- $E$  : total energy use (kWh)
- $M$  : total production capital (Rp)
- $PF_i$  : profit of production alternative  $i$  (Rp)
- $P_j$  : product  $j$
- $T$  : total man-hours required (hours)
- $X_i$  : production alternative  $i$
- $Cm_{ji}$  : RTB material cost of product  $j$  production alternative  $i$  (Rp)
- $y_{ji}$  : number of product  $j$  produced by alternative  $i$  (unit).
- $v_j$  : volume of RTB used for producing product  $j$  ( $m^3$ )
- $CM$  : unit price of RTB (Rp/unit)
- $S_{ji}$  : selling price of product  $j$  (Rp)
- $SR_i$  : income resulted from selling the waste of production alternative  $i$  (Rp)
- $Cm_i$  : material cost of production alternative  $i$  (Rp)
- $CL_i$  : labor cost of production alternative  $i$  (Rp)
- $CE_i$  : energy cost of production alternative  $i$  (Rp)
- $CO_i$  : overhead cost of production alternative  $i$  (Rp)
- $y_{ji}$  : number of product  $j$  produced by production alternative  $i$  (unit)

### 2.2 Production Cost and Profit

The problem is solved by production alternatives approach. Firstly, the railway track bearing waste is simulated using AutoCAD 2006 to find alternative products may be produced. One of the simulations is shown in Figure 4. The result shows that there are three units of Oval Branch Lamp can be produced from one unit of RTB. Simulation results of production alternatives are presented at Table 3.

Figure 4: RTB simulation for production alternative 2

Table 3: Production alternatives of one unit of RTB

| No | Alternative ( $X_i$ ) | Quantity (units) |       |       |       |       |
|----|-----------------------|------------------|-------|-------|-------|-------|
|    |                       | $P_1$            | $P_2$ | $P_3$ | $P_4$ | $P_5$ |
| 1  | $X_1$                 | 1                |       |       |       |       |
| 2  | $X_2$                 |                  | 3     |       |       |       |
| 3  | $X_3$                 |                  | 1     | 1     |       | 2     |
| 4  | $X_4$                 |                  | 1     |       | 1     |       |
| 5  | $X_5$                 |                  | 1     |       |       | 6     |
| 6  | $X_6$                 |                  | 2     |       |       | 2     |
| 7  | $X_7$                 |                  |       | 2     |       |       |
| 8  | $X_8$                 |                  |       | 1     |       | 4     |
| 9  | $X_9$                 |                  |       |       | 1     | 2     |
| 10 | $X_{10}$              |                  |       |       |       | 10    |

RTB material cost of each product is calculated as follow:

$$Cm_{ji} = \frac{y_{ji}v_j}{\sum_{j=1}^5 y_{ji}v_j} \times CM \quad (1)$$

Calculation result of material cost of production alternatives is shown in Table 4. Using the data in Table 2, energy and labor cost of production alternatives can be calculated and the result is presented in Table 5. Overhead cost is usually 15% of production cost.

The production process yields wood scrap with selling price of Rp 100.000,-/ $m^3$ . The scrap is transported to the buyer using truck with 2% of volume reduction. Based on this data, production waste and its selling price can be calculated and the result is shown in Table 6.

Profit of each production alternative is calculated based on the income resulted from selling the products and waste, production cost, and overhead cost, which can be formulated as follow:

$$PF_i = \sum_{j=1}^n y_{ji}S_j + SR_i - \left[ (Cm_i + CL_i + CE_i + CO_i) + 0.15(Cm_i + CL_i + CE_i + CO_i) \right] \quad (2)$$

Using the data and calculation result presented previously, the profit of all production alternatives are calculated using Equation (2) and the result is shown in Table 7.

Table 4: Material cost of production alternatives

| Alternative<br>[ $X_i$ ] | Product<br>[ $P_j$ ] | Quantity<br>[ $V_{ji}$ ] | RTB material (Rp)      |                     | NonRTB material (Rp)   |                        |                                  |

| $X_9$                    | $P_4$                | 1                        | 0.044880                                   | 0.02112                      | 0.000422                         | 0.020698                             | 2070                                 |
|                          | $P_5$                | 2                        |  |                              |                                  |                                      |                                      |
| $X_{10}$                 | $P_5$                | 10                       | 0.026400                                   | 0.0396                       | 0.000792                         | 0.038808                             | 3881                                 |

Table 7: Profit of production alternatives

| Alternative [ $X_i$ ] | Profit [ $P_{Fi}$ ] (Rp) |
|-----------------------|--------------------------|
| $X_1$                 | 604804                   |
| $X_2$                 | 757636                   |
| $X_3$                 | 1084584                  |
| $X_4$                 | 582729                   |
| $X_5$                 | 1522804                  |
| $X_6$                 | 913257                   |
| $X_7$                 | 801984                   |
| $X_8$                 | 1240205                  |
| $X_9$                 | 738350                   |
| $X_{10}$              | 2132352                  |

The objective of the production is to maximize profit, and thus the objective function of the problem can be formulated as follow:

Maximize total profit

$$\begin{aligned}
 \text{Max } Z &= \sum_{i=1}^{10} P_{Fi} X_i \\
 &= 604804X_1 + 757636X_2 + 1084584X_3 + 582729X_4 \\
 &\quad + 1522804X_5 + 913357X_6 + 801984X_7 + 1240205X_8 \\
 &\quad + 738350X_9 + 2132352X_{10}
 \end{aligned} \quad (3)$$

The constraints of the problem include the demand of *lighting* products, energy availability, production capacity, and production capital. The company has 1560 kWh energy available in every month. The available man-hour is 1092 hours a month. Monthly financial resource for producing lighting product is limited to Rp. 200,000,000. With regard to the demand, the maximum monthly production of each product type is decided to be 50 units. Production capacity is represented by man-hours availability, which is 156 man-

hours per month. Hence, problem constraints can be formulated as follow:

$$P_1 : X_1 \leq 50 \quad (4)$$

$$P_2 : 3X_2 + X_3 + X_4 + X_5 + 2X_6 \leq 50 \quad (5)$$

$$P_3 : X_3 + 2X_7 + X_8 \leq 50 \quad (6)$$

$$P_4 : X_4 + X_9 \leq 50 \quad (7)$$

$$P_5 : 2X_3 + 6X_5 + 2X_6 + 4X_8 + 2X_9 + 10X_{10} \leq 50 \quad (8)$$

$$\begin{aligned}
 E : & 2.025X_1 + 1.746X_2 + 3.610X_3 + 1.789X_4 + 8.185X_5 \\
 & + 3.698X_6 + 0.989X_7 + 5.563X_8 + 3.741X_9 \\
 & + 12.672X_{10} \leq 1560
 \end{aligned} \quad (9)$$

$$\begin{aligned}
 T : & 13.124X_1 + 23.040X_2 + 25.718X_3 + 13.280X_4 \\
 & + 30.915X_5 + 23.105X_6 + 20.586X_7 + 25.783X_8 \\
 & + 13.345X_9 + 38.725X_{10} \leq 1092
 \end{aligned} \quad (10)$$

$$\begin{aligned}
 M : & \sum_{i=1}^{10} C_i X_i \leq 200000000 \\
 & : 562196X_1 + 745457X_2 + 1050918X_3 \\
 & \quad + 540733X_4 + 1380986X_5 + 890444X_6 \\
 & \quad + 865837X_7 + 1195905X_8 + 685720X_9 \\
 & \quad + 1871529X_{10} \leq 200000000
 \end{aligned} \quad (11)$$

$$X_{1,...,10} \geq 0 \quad (12)$$

### 3. OPTIMAL SOLUTION

The problem is a linear programming and is solved using LINGO *software* with integer value on the production alternatives ( $X_i$ ). The optimal solution of the problem is shown in Table 8

Table 8: Optimal production

| No.   | Production alternative ( $X_i$ ) | Quantity (sets of production) | Products Quantity (units) |       |       |       |       |
|-------|----------------------------------|-------------------------------|---------------------------|-------|-------|-------|-------|
|       |                                  |                               | $P_1$                     | $P_2$ | $P_3$ | $P_4$ | $P_5$ |
| 1     | $X_1$                            | 50                            | 50                        |       |       |       |       |
| 2     | $X_2$                            | 0                             |                           |       |       |       |       |
| 3     | $X_3$                            | 0                             |                           |       |       |       |       |
| 4     | $X_4$                            | 6                             |                           | 6     |       | 6     |       |
| 5     | $X_5$                            | 0                             |                           |       |       |       |       |
| 6     | $X_6$                            | 0                             |                           |       |       |       |       |
| 7     | $X_7$                            | 1                             |                           |       | 2     |       |       |
| 8     | $X_8$                            | 0                             |                           |       |       |       |       |
| 9     | $X_9$                            | 25                            |                           |       |       | 25    | 50    |
| 10    | $X_{10}$                         | 0                             |                           |       |       |       |       |
| Total |                                  |                               | 50                        | 6     | 2     | 31    | 50    |

Table 8 shows that the optimal production consists of 50 sets of production alternatives 1, 6 sets of production alternatives 4, 1 set of production alternatives 7, and 25 sets of production alternatives 9. In other word, in order to get maximum profit the monthly production of the company should be 50 units of Bima Lamp ( $P_1$ ), 6 units of Oval Branch Lamp ( $P_2$ ), 2 units of Neo Pedati Lamp ( $P_3$ ), 31 units of Megan Lamp ( $P_4$ ), and 50 units Natural Erosi Lamp ( $P_5$ ). That production needs 82 units of railway track bearing waste, 206,498 kWh of electrical energy, 1090,091 man-hours, and Rp 49,363,035,- of capital. The optimal production results in 52,997,310,- of profit. Table 9 shows the breakdown of optimal production cost.

Table 9: Optimal production cost

| Product | Material cost (Rp) | Energi cost (Rp) | Labor cost (Rp) | Total cost (Rp) | Cost per unit (Rp) |
|---------|--------------------|------------------|-----------------|-----------------|--------------------|
| $P_1$   | 14454100           | 56700            | 3682500         | 18193300        | 363866             |
| $P_2$   | 794742             | 1955             | 249750          | 1046447         | 174408             |
| $P_3$   | 511448             | 554              | 115900          | 627902          | 313951             |
| $P_4$   | 4272388            | 20954            | 1001300         | 5294642         | 170795             |
| $P_5$   | 6352000            | 35481            | 1124600         | 7512081         | 150242             |
| Total   | 26384678           | 115644           | 6174050         | 32674372        |                    |

Table 9 shows that material cost has the highest contribution to the production cost. In this case Bima Lamp ( $P_1$ ) is the highest contributor. The table also shows that compared to the other products the production of Bima Lamp ( $P_1$ ) has the highest unit production cost. Therefore, the company should improve their productivity by increasing the efficiency of energy use and labor-based process in particular for Bima Lamp. Besides improving process productivity, it is important to the company to find alternative materials as substitutes for the materials that are currently used. The secondary materials should be cheap but qualified enough in order to make the products competitive

#### 4. CONCLUSION

We have presented an optimization model of the use of railway track bearing waste for producing lighting products. The model was basically developed based on the case of lighting production at PT Lunar Mulia Kreasi, Yogyakarta Indonesia. The model was to maximize profit with regard to the demand and resource availabilities.

The problem was solved using production alternatives approach and formulated as a linear programming with

integer value on the production alternatives. Optimal solution was then determined using LINGO.

PT Lunar Mulia Kreasi can be acknowledged as an environmental conscious manufacturing company. By using railway track bearing waste to produce lighting products the company has considered waste as an alternative resource for producing goods while simultaneously reduces the rate of environmental depletion. However, the utilization of railway track bearing waste for lighting production may generate waste and emission that have environmental impact. Therefore, the optimization of utilizing railway track bearing waste for lighting production could be extended by considering economic and environmental aspects simultaneously.
